

9.04 The Methane Abundance and Structure of Cloud Bands on Uranus

L. A. Sromovsky and P. M. Fry

University of Wisconsin - Madison
Space Science and Engineering Center

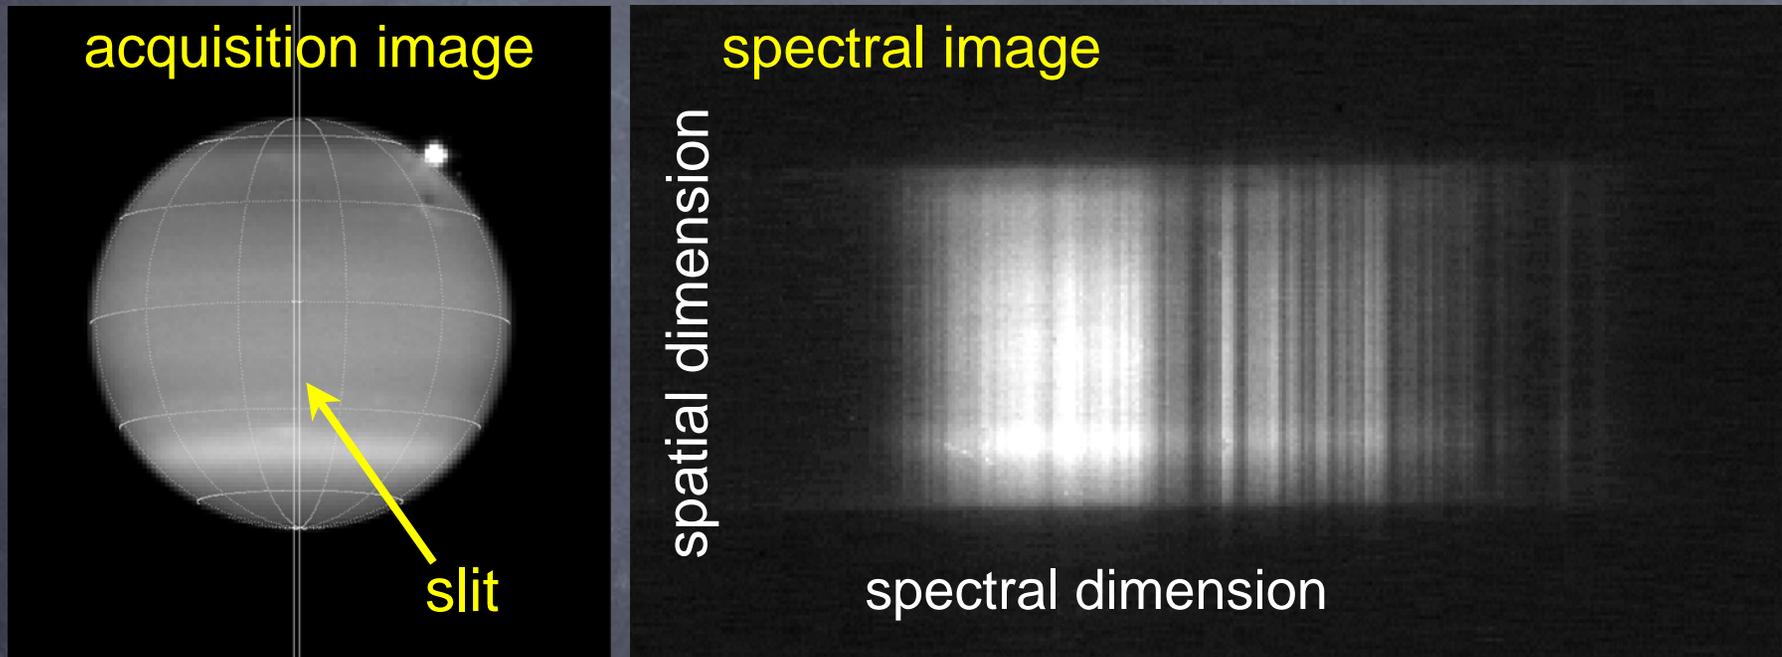

8 October 2007,
39th DPS Meeting, Orlando Florida

Date: October 2006

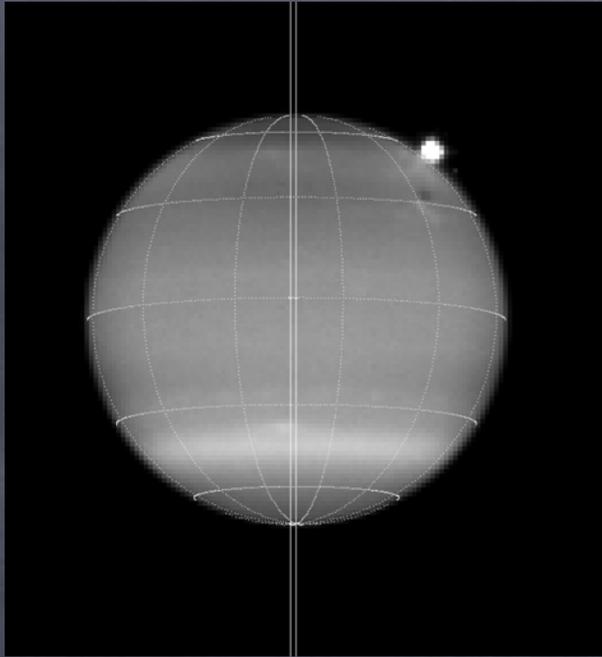

Telescope: Keck II with Adaptive Optics

Instrument: NIRC2, grism

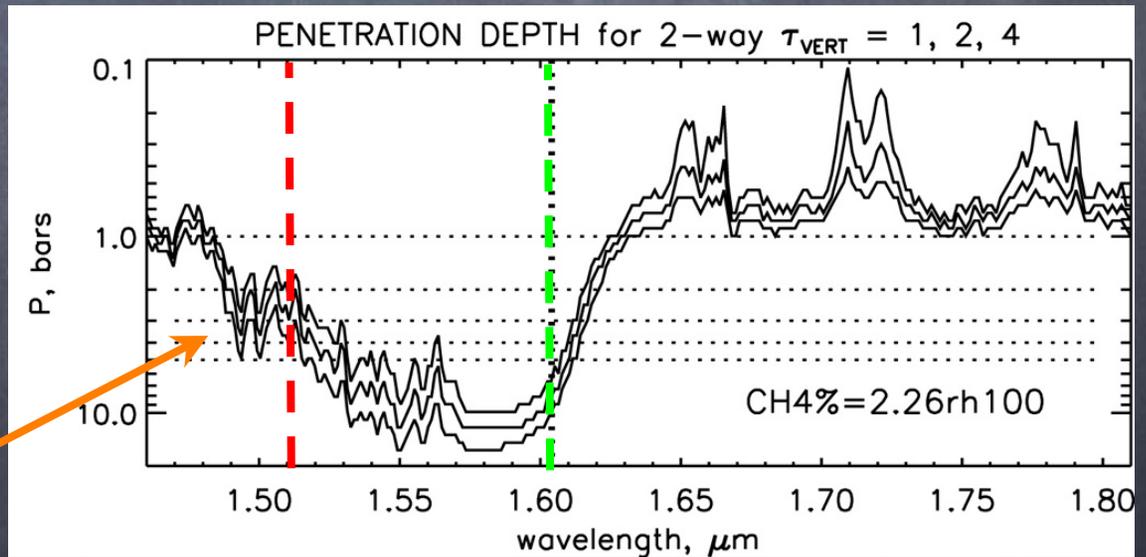

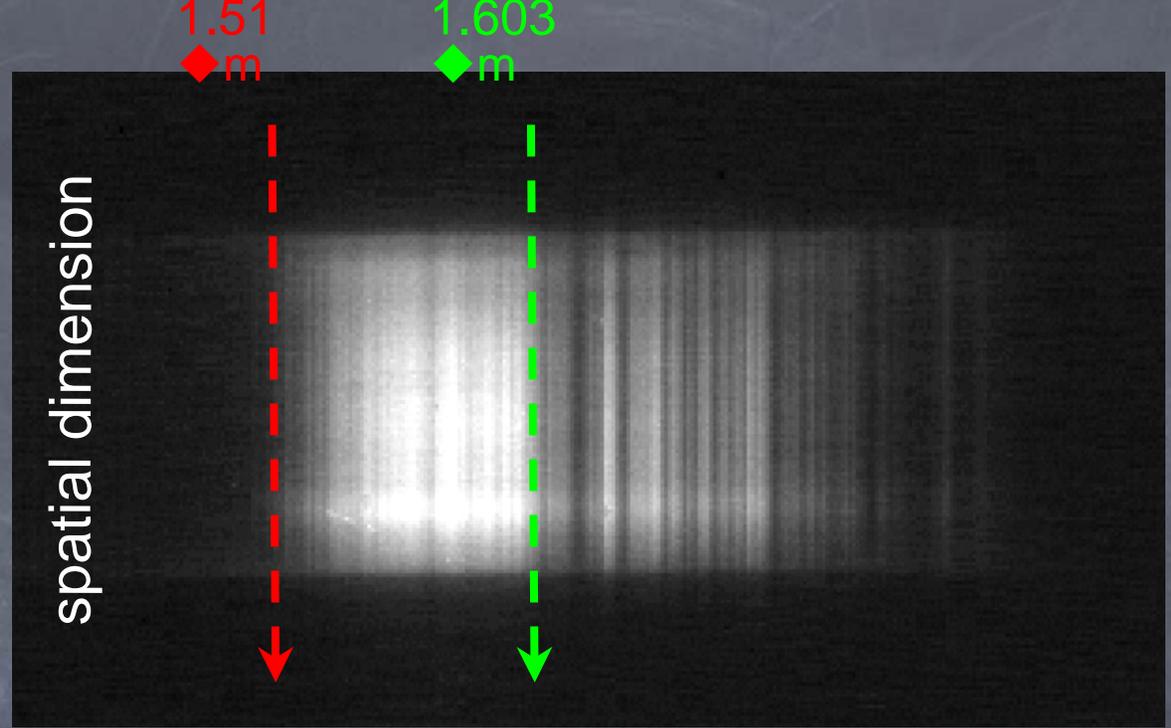

Measurements: spatially resolved central-meridian
spectra in J and H bands.

OBJECTIVES: Constrain the CH₄ mixing ratio.
Locate the Uranus cloud layers in pressure.
Determine composition of cloud layers.

spatial scans at different wavelengths sample different atmospheric levels

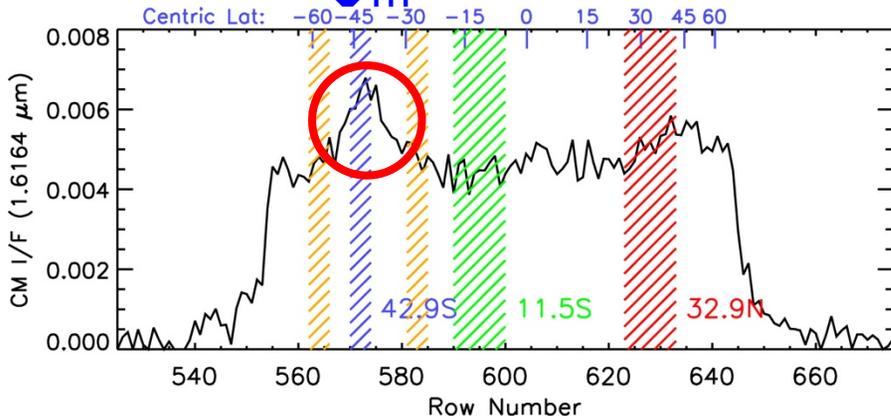

2.5-4 bars

7-10 bars

Pressures at which $a=0$ to $a=1$ change in surface produces I/F change of $1/e$, $1/e^2$, $1/e^4$ or 0.36, 0.13, 0.02.

1.6164

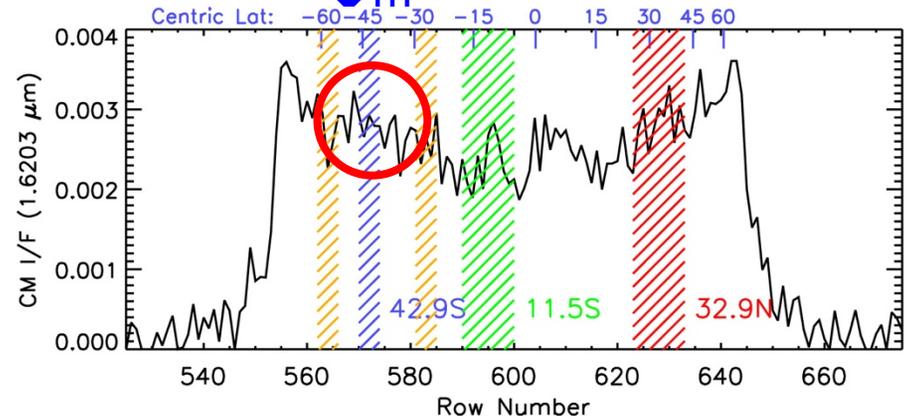

◆ m

the bright band is seen above the 2-3 bar level

1.6203

◆ m

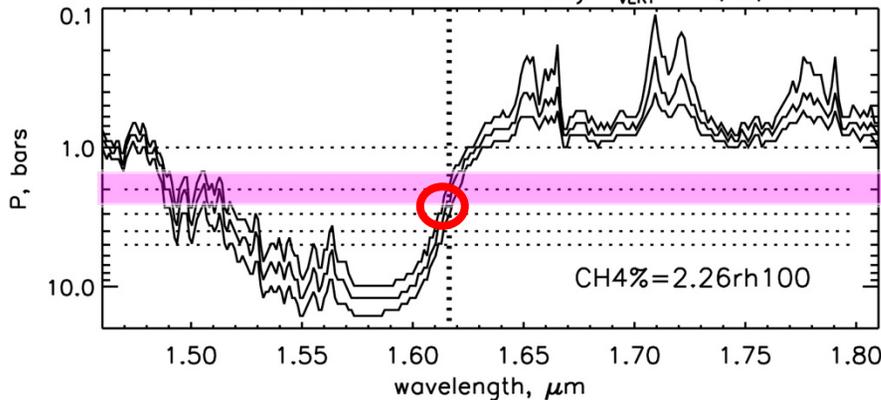

the bright band is not seen above the 1.5-bar level

part of the bright band is between 1.7 bars and 2.5 bars

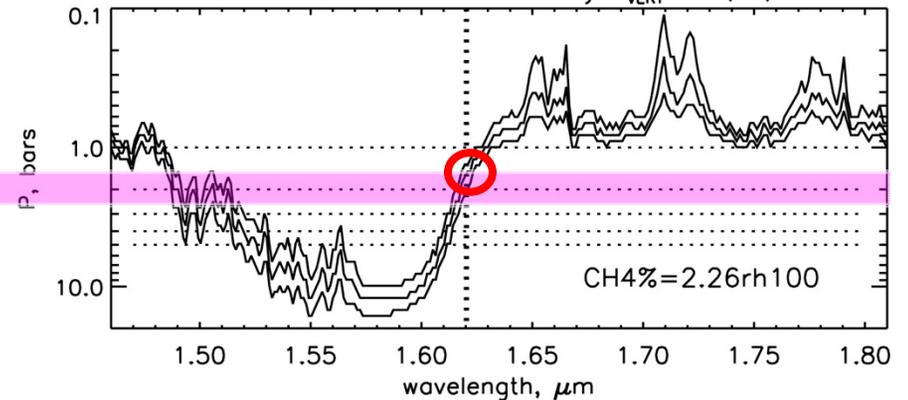

2-3 bars

PENETRATION DEPTH for 2-way $\tau_{\text{VERT}} = 1, 2, 4$

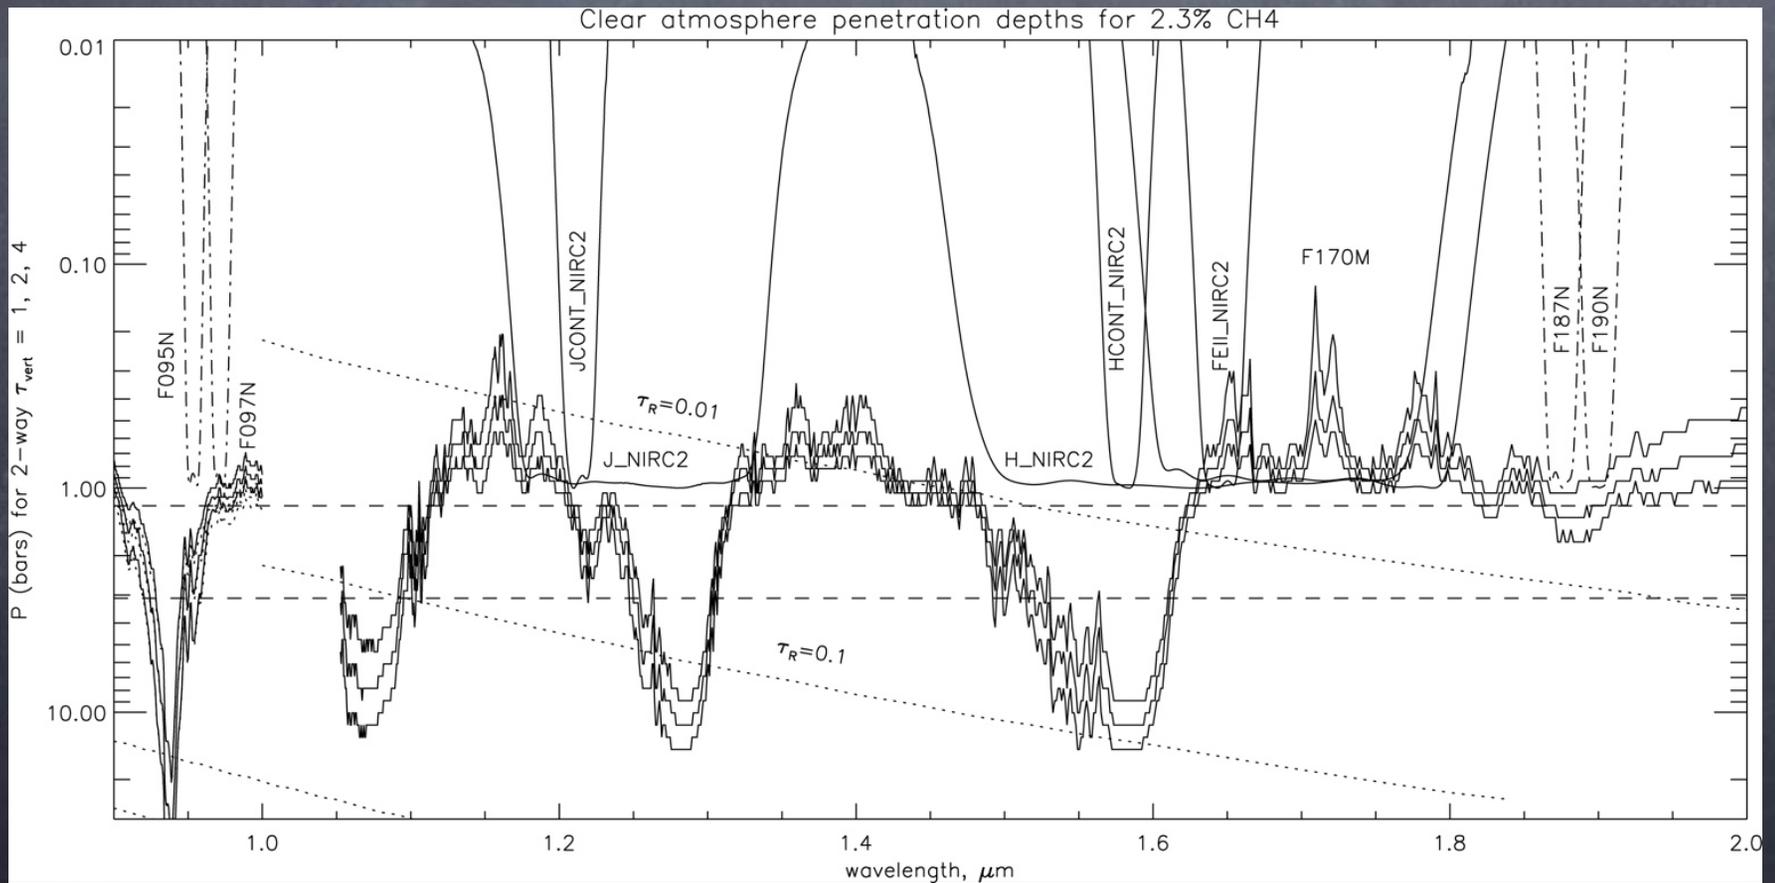

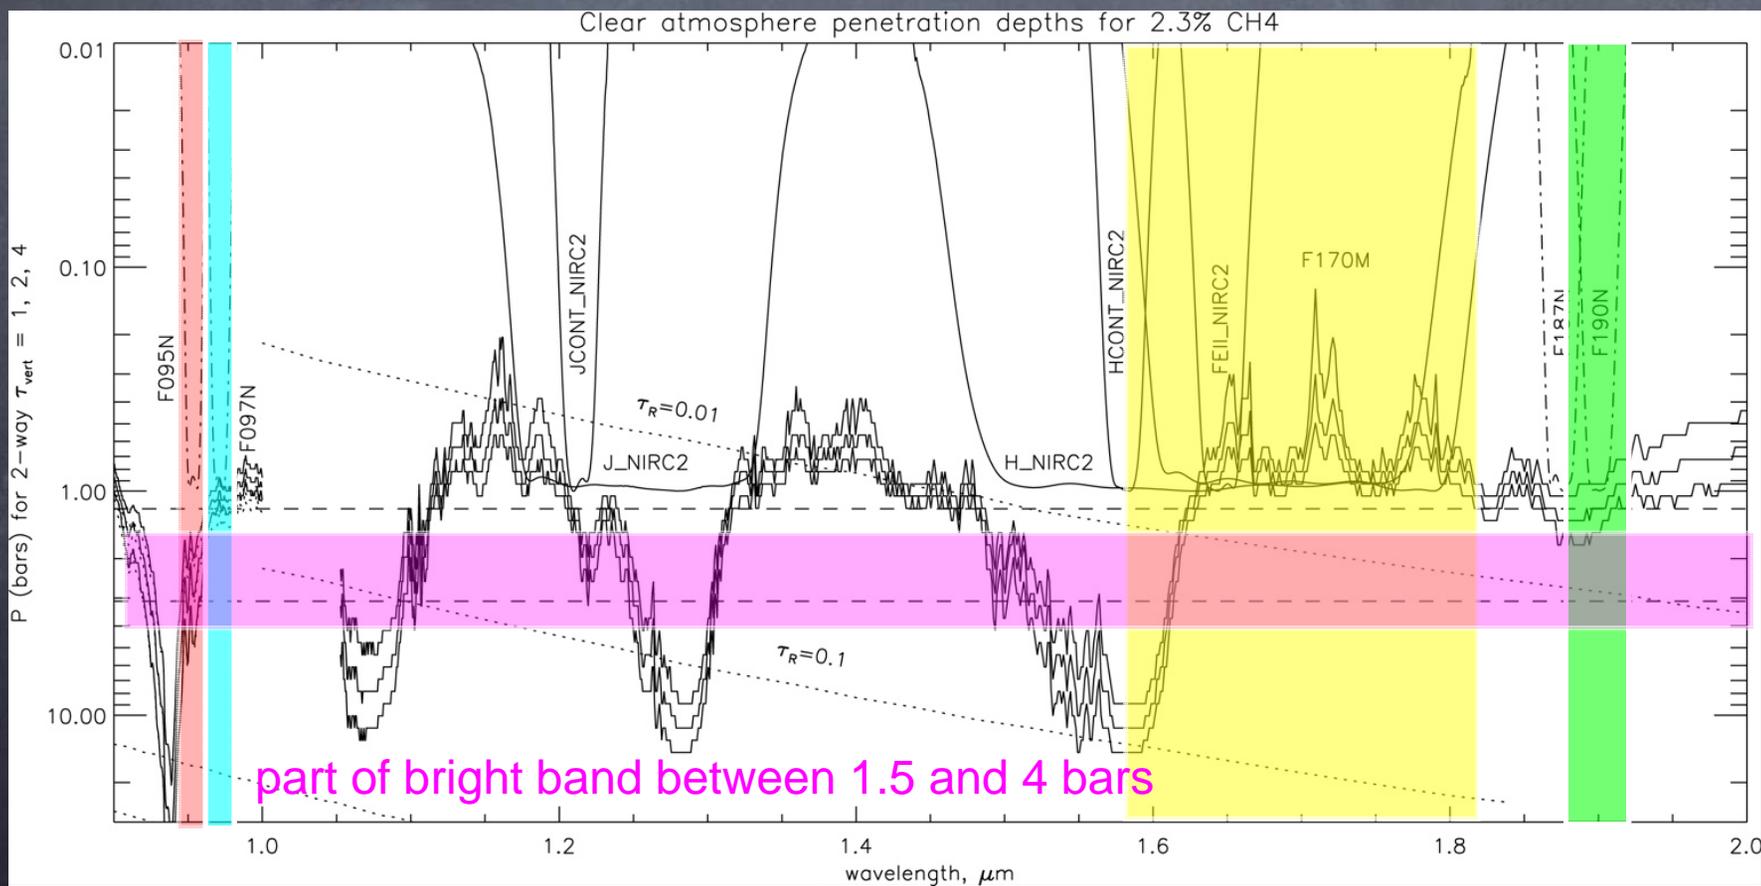

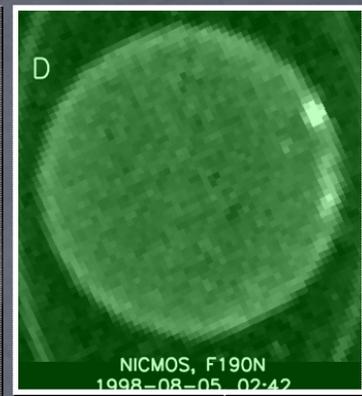

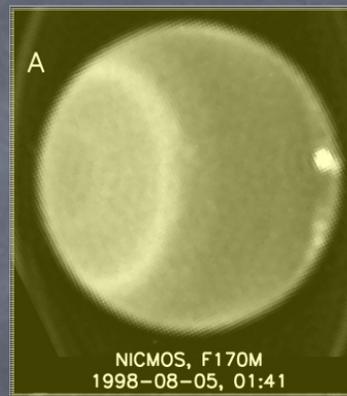

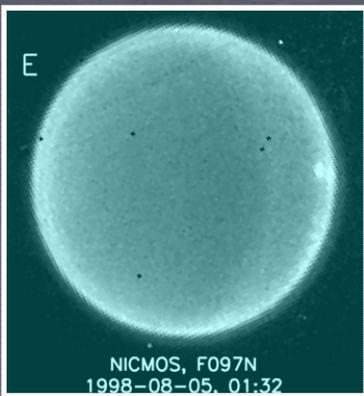

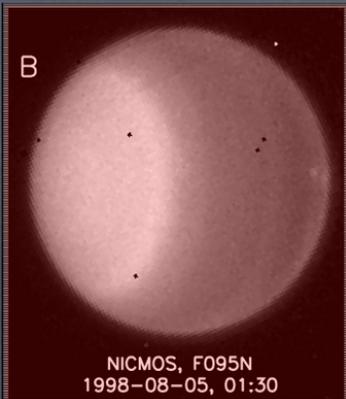

1.3-2 bars

PENETRATION DEPTH for 2-way $\tau_{\text{VERT}} = 1, 2, 4$

the bright band location is verified
by bandpass filter imaging

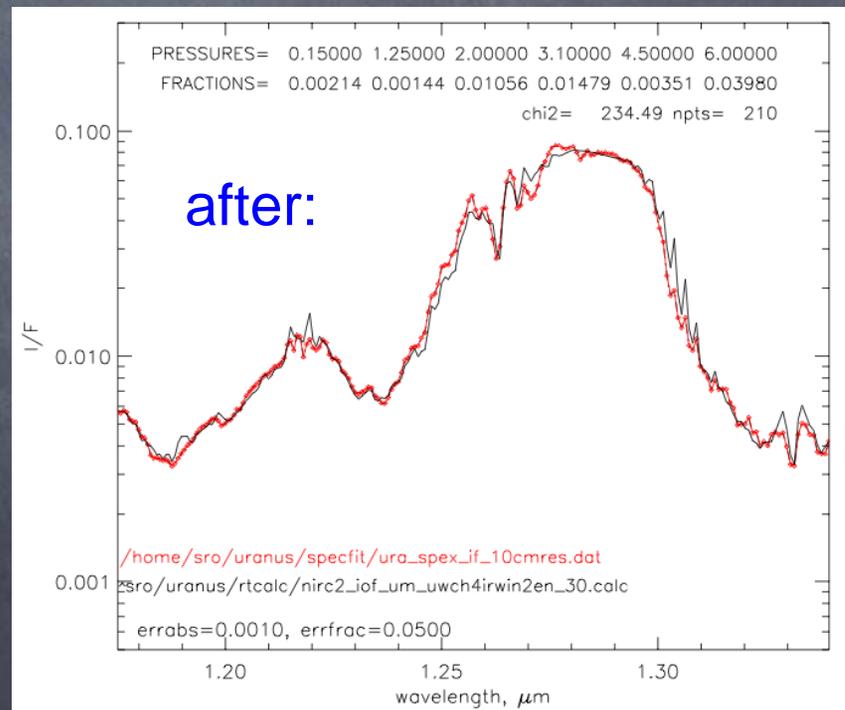

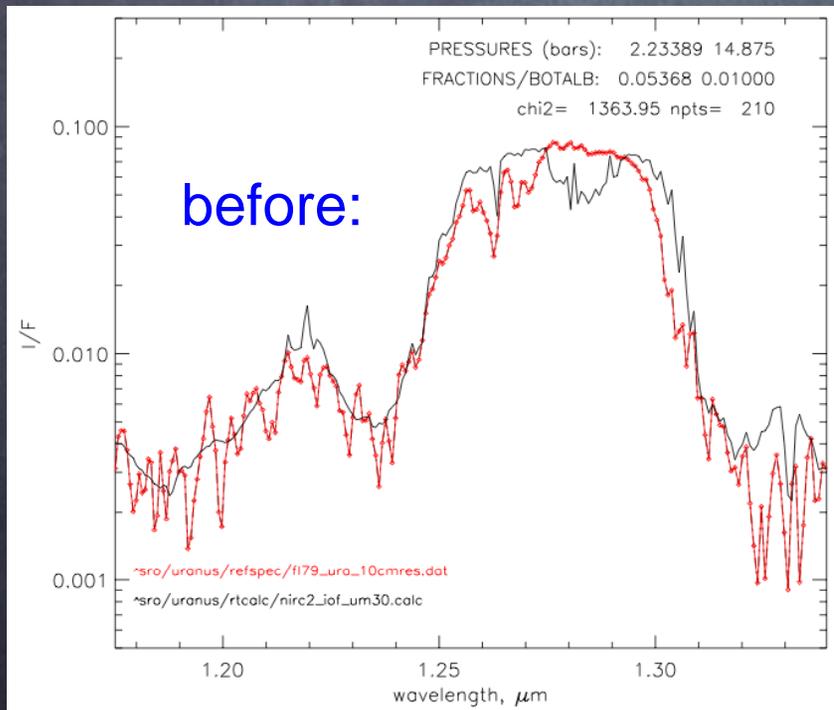

using spectral fits to constrain cloud
structure models

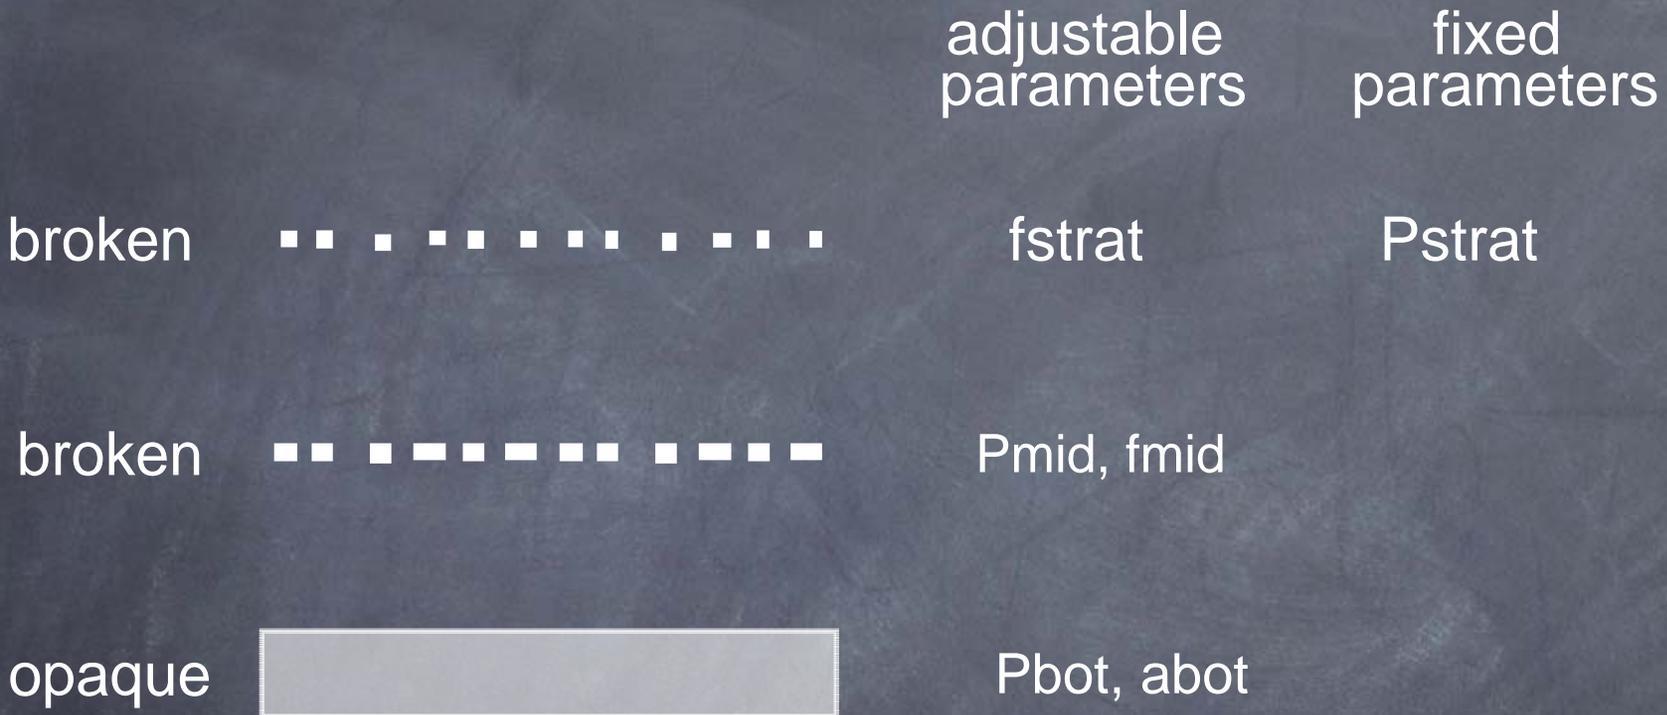

Recent improvements in modeling methane absorption:

Sromovsky, L.A., Irwin, P.G.J., Fry, P.M. 2006 Near-IR methane absorption in outer planet atmospheres: **Improved models of temperature dependence** and implications for Uranus cloud structure. Icarus 182, 577-593.

Irwin, P.G.J., Sromovsky, L.A., Strong, E.K. Sihra, K. Bowles, N. Calcutt, S. B. Remidios J.J. 2006, Fry, P.M. **Improved near-infrared methane band models and k-distribution parameters** from 2000 to 9500 cm⁻¹ and implications for interpretation of outer planet spectra. Icarus 181, 309-319.

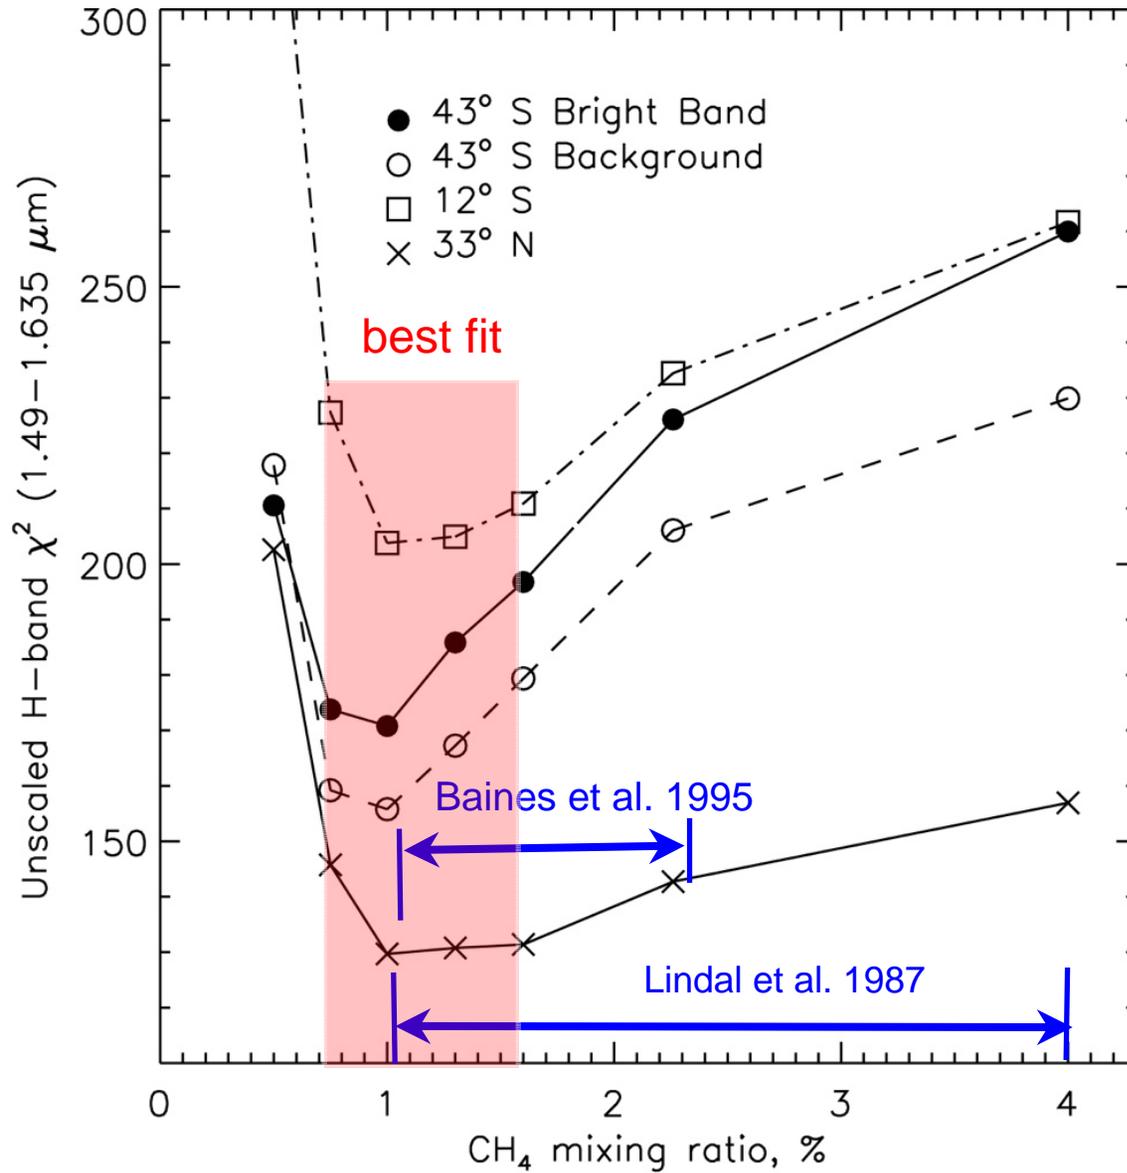

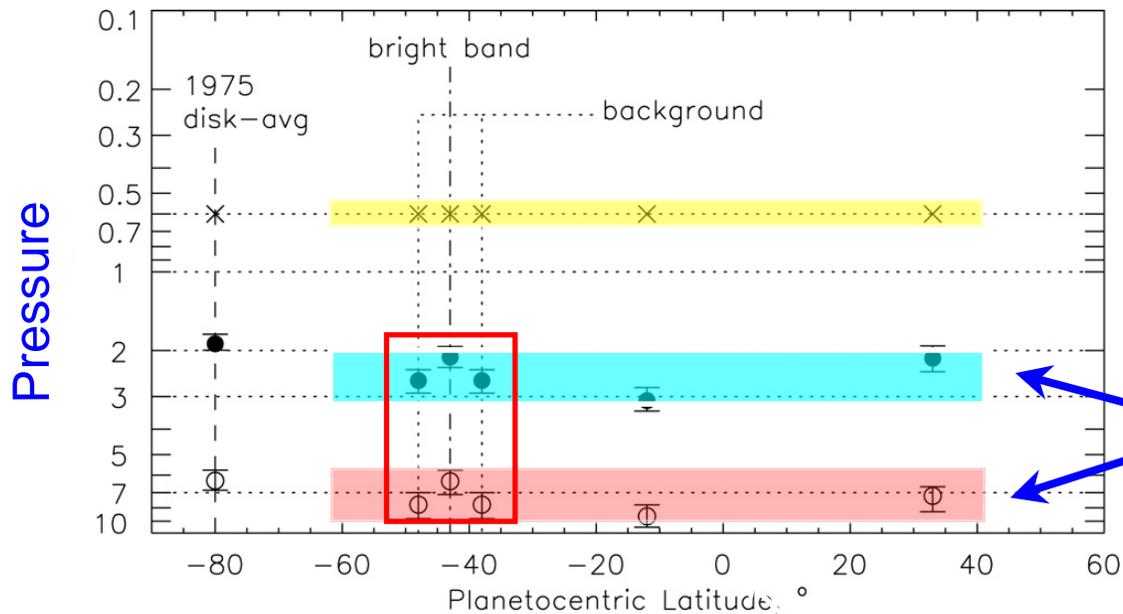

a simple reflecting layer model of cloud structure

$$I(\lambda) = f_{\text{strat}} \times I_1(P_{\text{strat}}, \lambda) + f_{\text{mid}} \times I_1(P_{\text{mid}}, \lambda) + (1 - f_{\text{strat}} - f_{\text{mid}}) \times [a_{\text{bot}} \times I_1(P_{\text{bot}}, \lambda) + (1 - a_{\text{bot}}) \times I_0(P_{\text{bot}}, \lambda)]$$

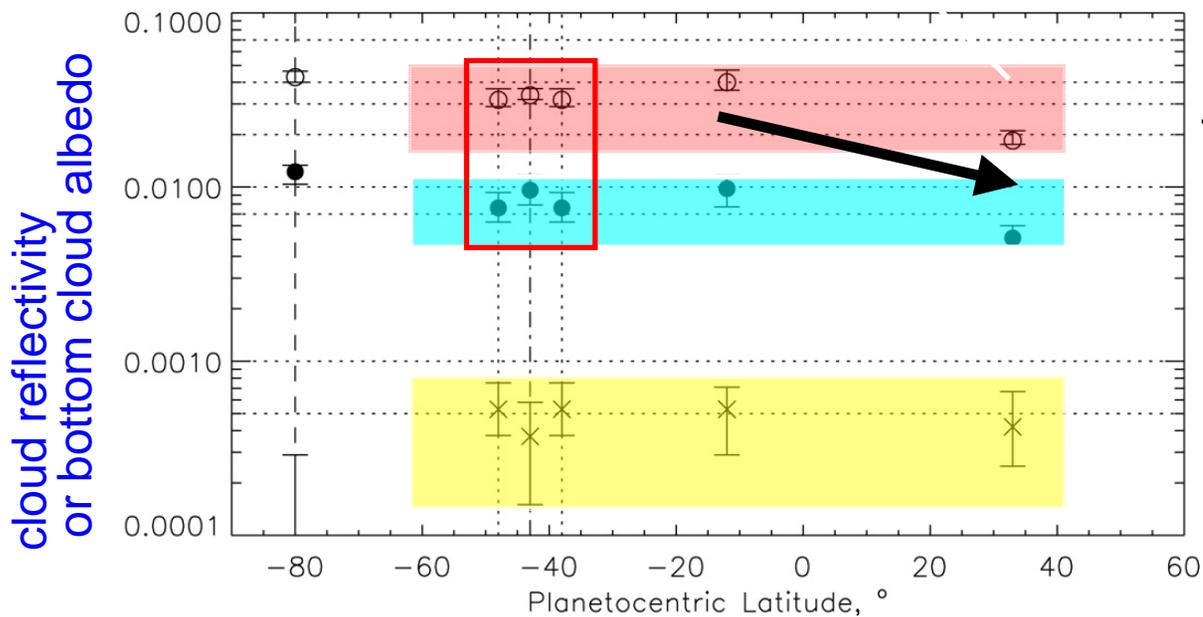

effect of CH₄ mixing ratio on H-band fit quality

In the bright band clouds are more reflective and at a lower pressure

Main clouds are near 2-3 bars and 7 bars at all lats.

The dark northern hemisphere is due to lower reflectivity of main clouds (50% lower at 35 N)

SUMMARY

- 1.0+/-0.3% CH₄ provides best fits to H spectra at most latitudes (lower than prior estimates of 1.6% and 2.3%)
- There is no significant cloud contribution at the methane condensation level (near 1.2-1.3 bars), nor at the expected level of 3.8 bars from prior analyses.
- Bandpass filter images confirms lack of band structure at 1.2-bar methane condensation level.
- Instead we find the main clouds are near 2-3 bars and 7 bars, slightly lower at higher CH₄ mixing ratios (similar pressures found from analysis of 0.6-0.83 micron STIS spectra; presented in Fry and Sromovsky poster 55.03).
- The darker northern hemisphere is due to lower reflectivity of the main clouds near 2 bars and 7 bars.
- The bright band is due to increased reflectivity and lower pressure of main clouds (both vary across bright band).
